

The cyclocross model of the frame is constructed completely by us, that means from the original design conception of the custom model on our computer modeling software, through detailed silver soldering of all weld points, to grinding and cleaning the joints. The frame is constructed from steel tubes made by Columbus, which are triple-butteted steel tubes Spirit HSS. The NIOBIUM alloy tubes were developed, so that the finished frame would have all the best mechanical properties with the least amount of weight possible without compromise of integrity.

Construction of the CX model was designed so that the lower part of the frame would have higher rigidity for better smoother power transmission. This was accomplished by profiling the lower frame tube while choosing the rear stays, which in the S-bend design ensures excellent throughput of the wheel in adverse conditions. The top tube is flattened vertically for greater flexibility and assists in absorption of road bumps. For the rider this bike becomes comfortable in all terrains, but due to constructional design also gives the rider the best prerequisite for technical ride.

When designing the frame, the emphasis was on functionality and all the cables are run on the outside. This allows the rider ability to easily carry the bike on their shoulder while climbing a hill. By adding a removable hanger eliminates the risk of impact damage. The customer is able to choose from a wide array of our recommended manufacturers of carbon forks, while our frames are adapted for cone placement of the headset to achieve better torsional stiffness.
